System and Method for Verifying Database Security Across Multiple Platforms

ABSTRACT

A system and method for verifying database security across multiple platforms is presented. Servers are queried to obtain a user id access list of a particular database, directory, or file. The user id access list is compared with a validated access list. A report file is generated that includes user id's that have access to a database, directory, or file but do not have proper permission. The report file includes a submission of how to correct each security violation.
